# Recursion

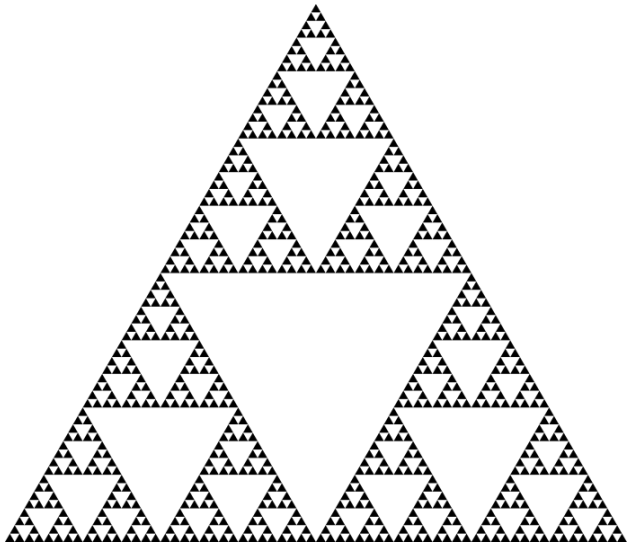
# Announcements

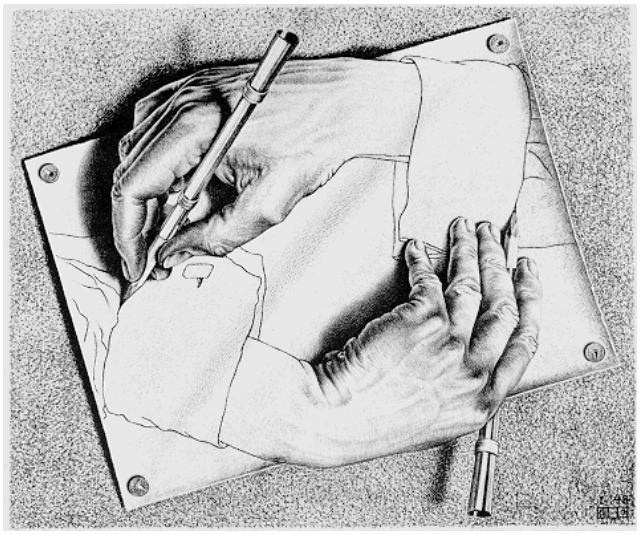
# Recursive Functions

# Recursive Functions

**Definition:** A function is called recursive if the body of that function calls itself, either directly or indirectly

**Implication:** Executing the body of a recursive function may require applying that function



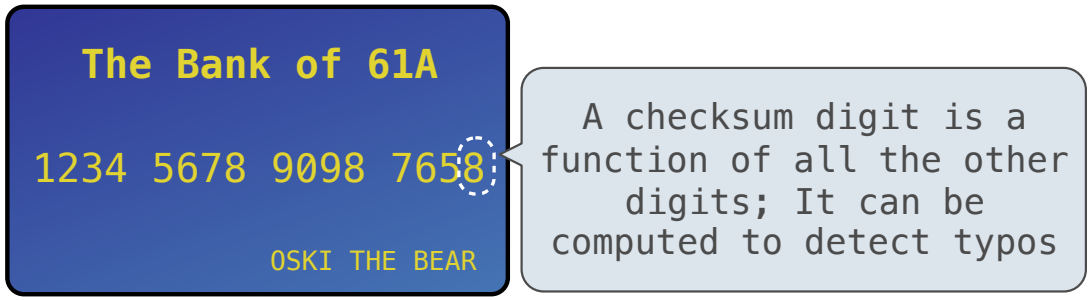


Drawing Hands, by M. C. Escher (lithograph, 1948)

# Digit Sums

**2+0+1+9 = 12**

- If a number a is divisible by 9, then `sum_digits(a)` is also divisible by 9
- Useful for typo detection!



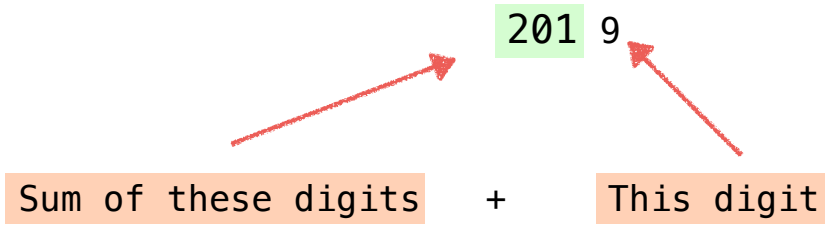
- Credit cards actually use the Luhn algorithm, which we'll implement after `sum_digits`

## The Problem Within the Problem

The sum of the digits of 6 is 6.

Likewise for any one-digit (non-negative) number (i.e., < 10).

The sum of the digits of 2019 is



That is, we can break the problem of summing the digits of 2019 into a smaller instance of the same problem, plus some extra stuff.

We call this recursion

## Sum Digits Without a While Statement

```
def split(n):
    """Split positive n into all but its last digit and its last digit."""
    return n // 10, n % 10

def sum_digits(n):
    """Return the sum of the digits of positive integer n."""
    if n < 10:
        return n
    else:
        all_but_last, last = split(n)
        return sum_digits(all_but_last) + last
```

# The Anatomy of a Recursive Function

- The `def statement header` is similar to other functions
- Conditional statements check for `base cases`
- Base cases are evaluated `without recursive calls`
- Recursive cases are evaluated `with recursive calls`

```
def sum_digits(n):
    """Return the sum of the digits of positive integer n."""
    if n < 10:
        return n
    else:
        all_but_last, last = split(n)
        return sum_digits(all_but_last) + last
```

(Demo)

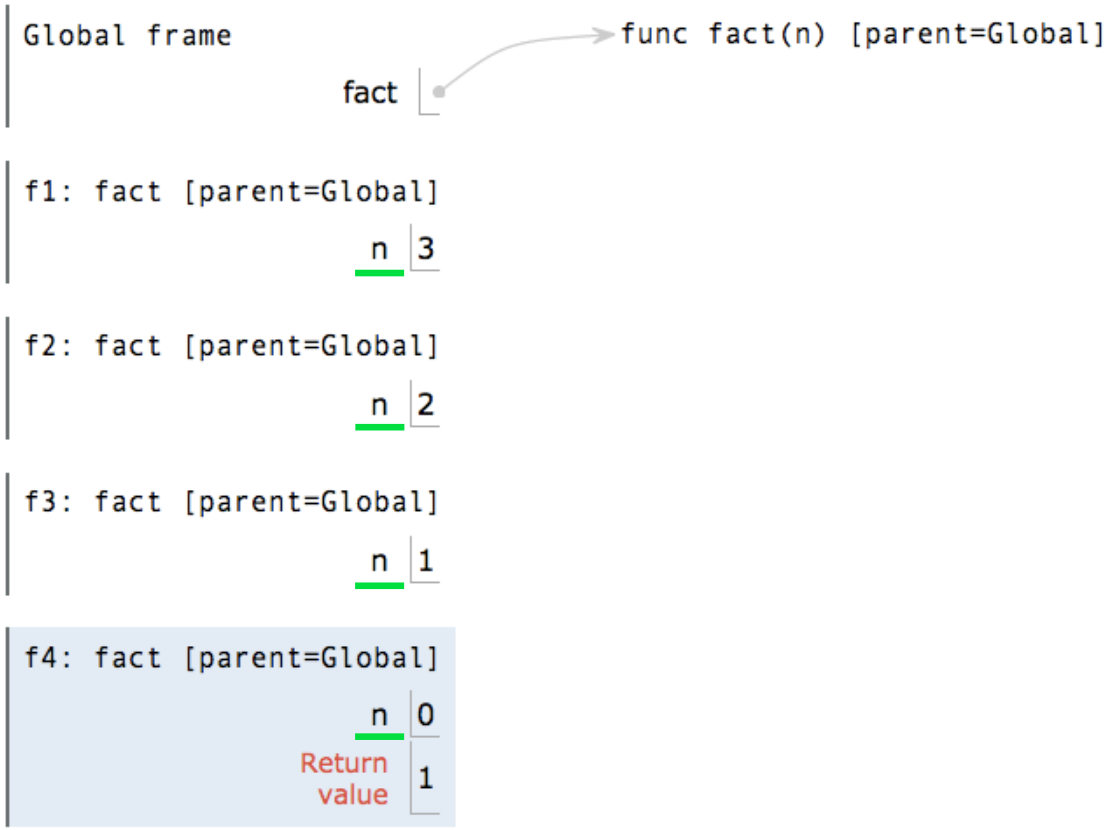
# Recursion in Environment Diagrams

# Recursion in Environment Diagrams

```
1  def fact(n):
2      if n == 0:
3          return 1
4      else:
5          return n * fact(n-1)
6
7  fact(3)
```

- The same function **fact** is called multiple times
- Different frames keep track of the different arguments in each call
- What **n** evaluates to depends upon the current environment
- Each call to **fact** solves a simpler problem than the last: smaller **n**

(Demo)



# Iteration vs Recursion

Iteration is a special case of recursion

$$4! = 4 \cdot 3 \cdot 2 \cdot 1 = 24$$

Using while:

```
def fact_iter(n):
    total, k = 1, 1
    while k <= n:
        total, k = total*k, k+1
    return total
```

Using recursion:

```
def fact(n):
    if n == 0:
        return 1
    else:
        return n * fact(n-1)
```

Math:

$$n! = \prod_{k=1}^{n} k$$

$$n! = \begin{cases} 1 & \text{if } n = 0 \\ n \cdot (n-1)! & \text{otherwise} \end{cases}$$

Names: `n, total, k, fact_iter`

`n, fact`

# Verifying Recursive Functions

# The Recursive Leap of Faith

```
def fact(n):
    if n == 0:
        return 1
    else:
        return n * fact(n-1)
```

Is fact implemented correctly?

1. Verify the base case

2. Treat **fact** as a functional abstraction!

3. Assume that **fact**(n-1) is correct

4. Verify that **fact**(n) is correct

# Mutual Recursion

# The Luhn Algorithm

Used to verify credit card numbers

From Wikipedia: http://en.wikipedia.org/wiki/Luhn_algorithm

- **First:** From the rightmost digit, which is the check digit, moving left, double the value of every second digit; if product of this doubling operation is greater than 9 (e.g., 7 * 2 = 14), then sum the digits of the products (e.g., 10: 1 + 0 = 1, 14: 1 + 4 = 5)
- **Second:** Take the sum of all the digits

| | | | | | |
|---|---|---|---|---|---|
| 1 | 3 | 8 | 7 | 4 | 3 |
| 2 | 3 | 1+6=7 | 7 | 8 | 3 |

= 30

The Luhn sum of a valid credit card number is a multiple of 10 (Demo)

# Recursion and Iteration

# Converting Recursion to Iteration

Can be tricky: Iteration is a special case of recursion.

Idea: Figure out what state must be maintained by the iterative function.

```
def sum_digits(n):
    """Return the sum of the digits of positive integer n."""
    if n < 10:
        return n
    else:
        all_but_last, last = split(n)
        return sum_digits(all_but_last) + last
```

A partial sum

What's left to sum

(Demo)

# Converting Iteration to Recursion

More formulaic: Iteration is a special case of recursion.

Idea: The state of an iteration can be passed as arguments.

```
def sum_digits_iter(n):
    digit_sum = 0
    while n > 0:
        n, last = split(n)
        digit_sum = digit_sum + last
    return digit_sum
```

Updates via assignment become...

```
def sum_digits_rec(n, digit_sum):
    if n == 0:
        return digit_sum
    else:
        n, last = split(n)
        return sum_digits_rec(n, digit_sum + last)
```

...arguments to a recursive call
